Let $\{X_i\}_{i=1}^n$ be i.i.d. random variables with common distribution function F .

Heavy-tailed models suggested by EVT:

There exist constants $a_n > 0$, $n \in \mathbb{N}$ such that

$$\lim_{n \rightarrow \infty} P\left\{\frac{\max(X_1, \dots, X_n)}{a_n} \leq x\right\} = \exp\left(-\left(1 + \frac{x}{\alpha}\right)^{-\alpha}\right),$$

for all x for which $1 + \alpha^{-1}x > 0$, $\alpha > 0$.

F is of **regular variation** at infinity of index $\alpha > 0$ if

$$\lim_{t \rightarrow \infty} \frac{1 - F(tx)}{1 - F(t)} = x^{-\alpha},$$

for all $x > 0$.

$$1 - F \in RV_{\alpha}$$

F is a **slowly varying** function if

$$\lim_{t \rightarrow \infty} \frac{1 - F(tx)}{1 - F(t)} = 1,$$

for all $x > 0$.

$$1 - F \in RV_0$$

Heavy tails:

Suppose there exists a positive function a such that F satisfies

$$\lim_{t \rightarrow \infty} \frac{F(tx) - F(t)}{a(t)} = \frac{1 - x^{-\alpha}}{\alpha},$$

for all $x > 0$, with $\alpha > 0$.

Super-Heavy tails:

$$\lim_{t \rightarrow \infty} \frac{F(tx) - F(t)}{a(t)} = \log x, \quad x > 0.$$

$$F \in ERV_{\alpha}, \alpha \geq 0$$

de Haan (1984)

Super-Heavy-tailed distributions

$$U(t) := \left(\frac{1}{1-F} \right)^{\leftarrow}(t) = \inf \left\{ x : F(x) \geq 1 - \frac{1}{t} \right\}$$

The following are equivalent:

$$F \in \Pi(a) : \quad \lim_{t \rightarrow \infty} \frac{F(tx) - F(t)}{a(t)} = \log x, \quad x > 0;$$

$$U \in \Gamma(q) : \quad \lim_{t \rightarrow \infty} \frac{U(t + xq(t))}{U(t)} = e^x, \quad x \in \mathbb{R},$$

with $q(t) = t^2 a(U(t))$, $a \in RV_0$

- » References

$$\hat{\alpha}_n(k) := \frac{2 \sum_{i=0}^{k-1} (X_{n-k,n} / X_{n-i,n})^2 - \sum_{i=0}^{k-1} (X_{n-k,n} / X_{n-i,n})}{\sum_{i=0}^{k-1} (X_{n-k,n} / X_{n-i,n}) - \sum_{i=0}^{k-1} (X_{n-k,n} / X_{n-i,n})^2}$$

$k = k_n$ is a sequence of positive integers such that $k_n \rightarrow \infty$ and $k_n = o(n)$ as $n \rightarrow \infty$ $\Rightarrow$ k_n is an intermediate sequence

Consistency: If $(n/\sqrt{k}) a(U(n/k)) \xrightarrow[n \rightarrow \infty]{} \infty$, then $\hat{\alpha}_n(k) \xrightarrow[n \rightarrow \infty]{P} \alpha \geq 0$.

Since $(n/k) a(U(n/k)) \xrightarrow[n \rightarrow \infty]{} \alpha$, we have that:

- for $\alpha > 0$, consistency holds for any intermediate sequence k_n ;
- for $\alpha = 0$, we need to impose a lower bound to the sequence k_n .

■ 2nd order Extended Regular Variation:

Suppose there exists a function $A(t) \rightarrow 0$, as $t \rightarrow \infty$, of constant sign near infinity and a second order parameter $\rho \leq 0$ such that

$$\lim_{t \rightarrow \infty} \frac{\frac{F(tx) - F(t)}{a(t)} - \frac{1 - x^{-\alpha}}{\alpha}}{A(t)} = \frac{1}{\rho} \left(\frac{x^{-\alpha+\rho} - 1}{-\alpha + \rho} + \frac{x^{-\alpha} - 1}{\alpha} \right) =: H_{\alpha, \rho}(x),$$

According to de Haan and Stadtmüller (1996), $|A(t)| \in RV_{\rho}$.

$$F \in 2ERV(\alpha, \rho), \alpha \geq 0, \rho \leq 0$$

Patterns of the estimated mean of $\hat{\alpha}_n(k)$

Patterns of the estimated mean of the Hill estimator

Let Y be a random variable with standard Pareto distribution.

A random variable W follows a log-Pareto distribution with parameter $\beta > 0$ if and only if $W = (e^{\beta Y} - 1) / \beta$.

... of the Hill estimator...

Consider a random sample taken from a standard log-Pareto population $X = e^Y$, with Y denoting a standard Pareto random variable. Then, the Hill estimator acquires the simple form

$$H_n(k) = \frac{1}{k} \sum_{i=0}^{k-1} Y_{n-i,n} - Y_{n-k,n}$$

Hence,

$$H_n(k) \stackrel{d}{=} Y_{n-k,n} \left(\frac{1}{k} \sum_{i=1}^k Y_i^* - 1 \right) = \frac{n}{k} (S_k + b_k) (1 + o_p(1)),$$

with $\{Y_i^*\}_{i=1}^k$ denoting i.i.d. standard Pareto random variables independent of the random threshold $Y_{n-k,n}$, $b_k = O(\log k)$ and where S_k denotes a random variable with limiting sum-stable distribution.

... of the Hill estimator...

Undertaking the log-Weibull distribution, the Hill estimator may be written as

$$H_n(k) = \frac{1}{k} \sum_{i=0}^{k-1} (\log Y_{n-i,n})^{1/\beta} - (\log Y_{n-k,n})^{1/\beta}$$

Hence,

$$\begin{aligned} H_n(k) &\stackrel{d}{=} (\log Y_{n-k,n})^{1/\beta-1} \frac{1}{\beta} \left(\frac{1}{k} \sum_{i=1}^k \log Y_i^* + o_p(1) \right) \\ &= \left(\log \frac{n}{k} \right)^{1/\beta-1} \frac{1}{\beta} (S_k^* + \sqrt{k}) (1 + o_p(1)), \end{aligned}$$

where S_k^* converges to a normal random variable.
