# Summary

- Basic Introduction to Neurosciences
  - Structure and function of the nervous system
  - Elements of Neuroanatomy
  - Neuronal signals
- Mathematical models for single units
  - Aims of models
    - First models
    - Hodgkin and Huxley type models
    - Stochastic models
  - Mathematical methods and related problems
- Models for assemblies of neurons
  - Aims of the models
    - Models of jump diffusion type
  - Mathematical methods and related problems
  - Alternative approaches and new researches topics

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

# Basic in Neurosciences

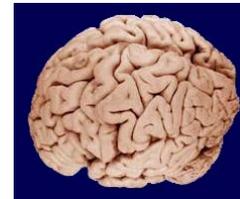

- The brain
  - Macroscopic level
  - Microscopic level
- Ideal neuron
  - Ideal neuron
  - Measurement techniques
  - Neuron activity
  - Electrophysiological properties
  - Spike trains
- .....some numbers.....
- Stochastic phenomena in neurobiology
- Mathematical/computer sciences approaches
  - Macroscopic level
  - Microscopic level

# The Brain: macroscopic level

The **frontal lobes** are involved in motor function, problem solving, spontaneity, memory, language, initiation, judgement, impulse control, and social and sexual behavior.

The **parietal lobes** can be divided into two functional regions. One involves sensation and perception and the other is concerned with integrating sensory input, primarily with the visual system.

The **occipital lobes** are the center of our visual perception system.

The **cerebellum** is involved in the coordination of voluntary motor movement, balance and equilibrium and muscle tone.

The **temporal lobes** are involved in the primary organization of sensory input

Bio-Math Summer School

## Brain: macroscopic level

- New exciting discoveries about brain physiology appear in the scientific literature each year, often uncovering a relatively isolated aspect of brain dynamics or its relationships with pathological conditions.
- Large-scale knowledge of the nervous system is generally only casted in psychological terms, with little discussion of underlying mechanisms (and its mathematical description).
- Exciting goal: to explain all macroscopic phenomena - regardless of their nature on the basis of their underlying microscopic dynamics (as it is in physics)

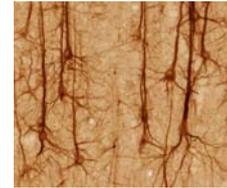

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Microscopic level

- Intricate network with triangular or circular cell bodies and long wire like expansion.
  - Elements: neurons (electrically excitable cells that process and transmit information) and glia cells (energy suppliers and structural stabilizers)
  - Signal is transmitted from a neuron to the next through synapses

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

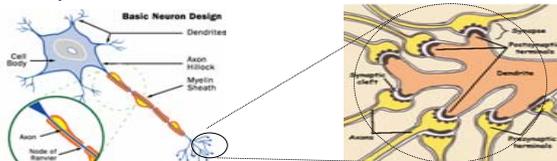

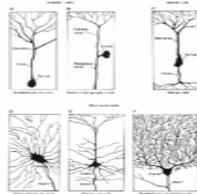

## Ideal neuron

Three functionally distinct parts: dendrites, soma and axon

- dendrites: input device collecting signals
- soma: central processing unit (nonlinear)
- axon: output device

Junction between two neurons: synapses (presynaptic, postsynaptic):  
**chemical** neurotransmitter (receptors in postsynaptic membrane;  
**electrical**)

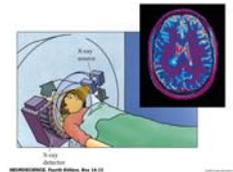

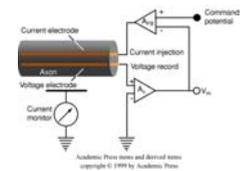

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Measurement Techniques

- Single Neuron Electrical activity
  - Intracellular - typically in brain slices
    - Current Clamp - measures voltage
    - Voltage Clamp - measures current
    - Patch clamp - measure single channel activity
  - Extracellular - typically in vivo
    - Measures action potentials
    - One or more neurons at a time
- Intracellular molecules
- Local field potentials
  - Average electrical activity produced by collections of neurons
- Electroencephalograph (EEG)
  - Average electrical activity produced by entire brain
- Whole brain activity in three dimensions

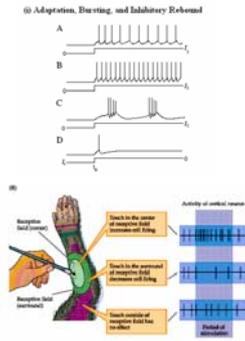

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

# Neuron activity

## Types of measurements of neuronal activity:

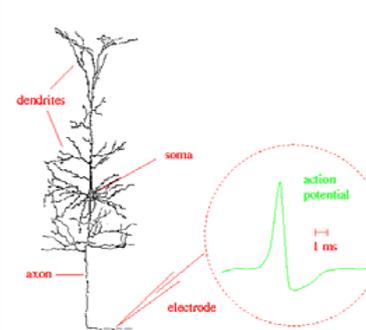

- Intracellular:  $V(t)$  membrane potential. Difference between interior and surrounding. In absence of inputs spontaneously decays toward a resting value ( $\sim -65$  mV)
- Extracellular: Potential adjacent to neuron is compared with potential further away. Measure signal in response to behavior

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

# Electrophysiological properties of single neurons

Intracellular measures show a difference of potential between inside and outside the cell membrane of about  $-70$  mV

If the membrane potential is less than  $-70$  mV the cell is inhibited

If the membrane potential is larger than  $-70$  mV the cell is excited. When depolarization attains a sufficient level one observes an action potential.

Action potentials propagate along the axon

The action potentials is a short voltage pulse of 1-2ms of duration and amplitude of about 100 mV.

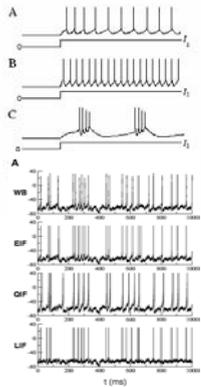

The action potentials of a specific neuron have a characteristic shape

Bio-Math Summer School

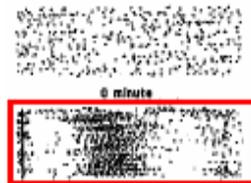

# Spike trains

## (i) Adaptation, Bursting, and Inhibitory Rebound

4 recordings

- Use of different scales disclose different properties.
- Using the raster displays one can observe spatio-temporal patterns
- Simultaneous recording show synchronization periods, delays,...

Raster display

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

# Some numbers

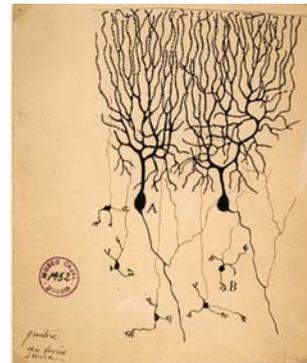

1mm  
10 000 neurons  
3 km fibers

Number of neurons in our brain  
>  $10^{12}$  neurons

30 years old people: neurons start to progressively expire and  $10^5$  neurons per day die after 70.  
...but  $10^6$  is only the 0,0001% of the total!

$10^3$  morphologically different neurons

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Other numbers

Mean number of synapses per neuron:  $10^4$

The developing brain generates between **50 and 100 thousand** new cells per second from the fifth through twentieth weeks of gestation.

**20-50 postsynaptic potentials**, in short time, allow the starting of a spike

A presynaptic neuron can be connected with **104** postsynaptic neurons

Neurons in the cerebral cortex of the brain can have a wiring density of up to **4km per mm<sup>3</sup>** by using incredibly thin axons as wires, with an **average diameter of 0.3 micrometers** (1 is one millionth of a meter).

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Complexity or overcomplexity????

How to deal with such overwhelming complex system?

Is there any role for mathematicians in such context?

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Stochastic phenomena in neurobiology

- Intrinsic noise sources:
  - Thermal noise (Johnson noise): the voltage across an electrical resistor  $R$  fluctuates at finite temperature: Source of minor importance.
    - The miniaturization economizes on space and energy but it increases the noise introduced by thermodynamic fluctuations in a neuron's voltage-gated ion channels
  - Number of ion open channels in a patch of neuronal membrane fluctuates
  - Neurotransmitters released by synapses
- Extrinsic noise sources
  - Synaptic transmission failure
    - Network effect: networks of excitatory and inhibitory neurons with fixed random connectivity. High number of connectivities

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Mathematical/Computer Science Approaches

- Macroscopic level
  - **Observed features:** synchronization phenomena, spatio-temporal pattern, specific areas activities
  - **Aim of models:** recover macroscopic behaviors and relate them with pathological (schizophrenia, epilepsy, tremor....) or health conditions
  - **Modeling approaches:**
    - brain as nonlinear system
    - Simulation of large networks through systems of differential equations
    - Computer simulated networks (object-oriented programs)

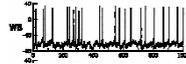

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Mathematical/Computer Science Approaches

- Microscopic level: single neuron or small networks
  - Observed features:
    - intracellular recordings (observation from a single neuron): membrane potential evolution and spike activity
    - extracellular recordings (possible simultaneous recording from 1-100 neurons): measures of the electrical field; spike sorting activity reveals spike activities
  - Aim of the models: recover observed features, forecast responses to specific stimuli
  - Modeling approaches (analytical, numerical and simulation methods):
    - Cable theory and related systems of equations (Hodgkin Huxley Models)
    - Threshold stochastic models (LIF models)

August 8-12, 2008 Middelfart, Denmark  
Bio-Math Summer School

## Mathematical models: historical hints

- Before 1952
- 1952 Hodgkin and Huxley model (Nobel laureate)
- Till Seventies: a golden period: many scientists cultivate the illusion to be proxime to "understand" the laws of the brain and the mind
- Till Eighties: main focus on single neuron activity models
- Ninties: a crisis period. Lack of mathematical results to support further improvements and slow entrance of computer science methods (simulations numerics). Single neuron models are used to understand specific features but a lack of mathematical instruments generate a sort of pessimism on attainability possible ambitious goals.
- ...new millenium: a new golden age? High speed computers and new techniques for simultaneous recording from groups of neurons open new challenges: mathematics methodologies are recognized an indispensable support for an interdisciplinary approach
